

Lists: The Personal Expense Tracker (Improved)

Overview

In this assignment, you will improve the personal expense tracker from last week. You will use python lists to keep track of expenses and print the top 3 expenses the user provided. To get started, ensure that you download the “Personal_Expense_Tracker_Improved.py” template file attached to this assignment in Blackboard. Use the “Load” button in Mu to load the attached template file and start your work. Do note that double-clicking a python file will attempt to run the file. This can make it appear as though the file opened and closes quickly but did nothing. In fact, the program ran and closed in that time. If you want to edit a file, you must load it into an editor as previously described.

You should only make the necessary changes to the template based on the TODO comments. The auto grader for this assignment will not work if you change the `display_total` function or if you change the code after the `#DO NOT CHANGE` comment in the main function.

Objectives

- To improve the Personal Expense Tracker.
- To practice writing and using lists in Python.
- To handle user input and perform basic arithmetic operations.
- To practice using tuples in Python.

Requirements

- Your program should accurately track and display the total expenses.
- It must handle invalid inputs gracefully without crashing.
- The final output should display the total expenses after the user is done entering expenses.
- Only modify the program where instructed via TODO comments. I have provided the solution for the previous weeks challenge, so you only need to focus on implementing these new features.

Functions to Implement

1. **main**
 - Update main to append each new expense and its description to their respective lists.
2. **get_top_expenses**
 - Traverse the `expenses_amt` list and determine the top three expenses.
 - Return a list of tuples containing the top 3 expenses
 1. For example: [(124.23, “Books”), (44.26, “Subscriptions”), etc....]
 1. This is just an example, you will return variable names, not literal values. I used literal values here to show you how the data should be structured.
