

Weather App – Optional Assignment

Overview

In this assignment, you will review web scraping in python and watch the “Weather Forecasting Project in Python” video on YouTube. This material covers interacting with web sites using Python code. In this assignment, you will code your own version of the weather app and demonstrate proficiency using the requests module in python and making API calls to request data. This assignment is auto graded. Carefully review the auto-grader output for tips on fixing any issues you run into.

Objectives

- Demonstrate how request information from an API using the request module.

Requirements

Write a program that satisfies the following:

- Import the `requests` module and use it to:
 - Get your `forecast` endpoint URL by requesting the information from the points API endpoint:
 - <https://api.weather.gov/points/{latitude},{longitude}>
 - You will need to get your latitude and longitude manually.
 - Example showing the “forecast endpoint URL in a sample of a return from the API:
...

```
"properties": {  
  "@id": "https://api.weather.gov/points/39.7456,-97.0892",  
  "@type": "wx:Point",  
  "cwa": "TOP",  
  "forecastOffice": "https://api.weather.gov/offices/TOP",  
  "gridId": "TOP",  
  "gridX": 32,  
  "gridY": 81,  
  "forecast": "https://api.weather.gov/gridpoints/TOP/32,81/forecast",  
}
```

...
 - Make a new request to the forecast endpoint URL you found in the last step. Print out the results for the first result in the periods list to show the “detailedForecast”. Do not print the detailedForecast for all periods in the periods list. This should print the current detailed forecast for your provided GPS coordinates. Feel free to have a little fun with it from here if you would like to!
